Cosmic rays in galaxy clusters

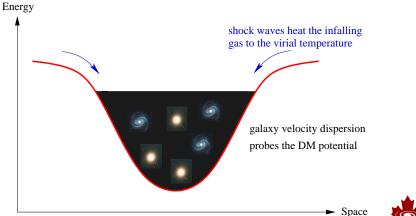

- Introduction and motivation
- Cluster simulations and cosmic ray physics
- Cosmic ray pressure feedback
- 2 Unified model of radio halos and relics
 - Radio emission from primary electrons
 - Hadronically produced radio emission
 - Towards a holistic view of cluster radio emission
- 3 Gamma-ray emission from clusters
 - Gamma-ray morphology
 - Gamma-ray scaling relations
 - Predicted cluster sample for GLAST

Introduction and motivation Cluster simulations and cosmic ray physics Cosmic ray pressure feedback

A theorist's perspective of a galaxy cluster ...

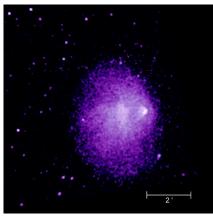

Galaxy clusters are dynamically evolving dark matter potential wells:

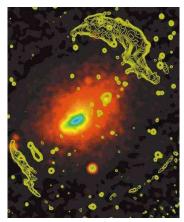

Introduction and motivation Cluster simulations and cosmic ray physics Cosmic ray pressure feedback

... and how the observer's Universe looks like

1E 0657-56 ("Bullet cluster")

(NASA/SAO/CXC/M.Markevitch et al.)

Abell 3667

(radio: Johnston-Hollitt. X-ray: ROSAT/PSPC.)

Introduction and motivation Cluster simulations and cosmic ray physics Cosmic ray pressure feedback

Observational properties of galaxy clusters

Each frequency window is sensitive to different processes and cluster properties:

- optical: gravitational lensing of background galaxies, galaxy velocity dispersion measure gravitational mass
- X-ray: thermal plasma emission, $F_X \propto n_{th}^2 \sqrt{T_{th}} \rightarrow$ thermal gas with abundances, cluster potential, substructure
- Sunyaev-Zel'dovich effect: IC up-scattering of CMB photons by thermal electrons, $F_{SZ} \propto p_{th} \rightarrow$ thermal gas pressure, cluster velocity, high-*z* clusters
- radio synchrotron halos: F_{synchro} ∝ ε_Bε_{CRe} → magnetic fields, CR electrons, shock waves
- diffuse γ -ray emission: $F_{\gamma} \propto n_{\text{th}} n_{\text{CRp}} \rightarrow \text{CR}$ protons

Introduction and motivation Cluster simulations and cosmic ray physics Cosmic ray pressure feedback

Why should we care about cosmic rays in clusters? It allows us to explore complementary windows to cluster cosmology

- Is high-precision cosmology possible using clusters?
 - Non-equilibrium processes such as cosmic ray pressure and turbulence possibly modify thermal X-ray emission and Sunyaev-Zel'dovich effect.
 - Cosmic ray pressure can modify the scaling relations → bias of cosmological parameters, or increase of the uncertainties if we marginalize over the 'unknown cluster physics' (cluster self-calibration)

What can we learn from non-thermal cluster emission?

- Estimating the cosmic ray pressure contribution.
- Constructing a 'gold sample' for cosmology using orthogonal information on the dynamical cluster activity.
- Fundamental physics: diffusive shock acceleration, large scale magnetic fields, and turbulence.

Introduction and motivation Cluster simulations and cosmic ray physics Cosmic ray pressure feedback

Philosophy and description

An accurate description of CRs should follow the evolution of the spectral energy distribution of CRs as a function of time and space, and keep track of their dynamical, non-linear coupling with the hydrodynamics.

We seek a compromise between

- capturing as many physical properties as possible
- requiring as little computational resources as necessary

Assumptions:

- protons dominate the CR population
- a momentum power-law is a typical spectrum
- CR energy & particle number conservation

Non-thermal emission from clusters Exploring the memory of structure formation

The thermal plasma lost most information on how cosmic structure formation proceeded due to the dissipative processes. The thermal observables, X-ray emission and the Sunyaev-Zel'dovich effect, tell us only very indirectly (if at all) about the cosmic history. In contrast, non-thermal processes retain their cosmic memory since their particle population is not in equilibrium \rightarrow cluster archaeology.

How can we read out this information about non-thermal populations? \rightarrow new era of multi-frequency experiments, e.g.:

- LOFAR, GMRT, MWA: interferometric array of radio telescopes at low frequencies ($\nu \simeq (15 240)$ MHz)
- Glast: international high-energy γ-ray space mission (E ~ (0.1 300) GeV)
- Imaging air Čerenkov telescopes (TeV photon energies)

ヘロト ヘヨト ヘヨト

Previous models for giant radio halos in clusters

Radio halos show a smooth unpolarized radio emission at Mpc-scales. How are they generated?

- Primary accelerated CR electrons: synchrotron/IC cooling times too short to account for extended diffuse emission.
- Continuous in-situ acceleration of pre-existing CR electrons either via interactions with magneto-hydrodynamic waves, or through turbulent spectra (Jaffe 1977, Schlickeiser 1987, Brunetti 2001, Brunetti & Lazarian 2007).
- Hadronically produced CR electrons in inelastic collisions of CR protons with the ambient gas (Dennison 1980, Vestrad 1982, Miniati 2001, Pfrommer 2004).

All of these models face theoretical short-comings when comparing to observations.

イロト イポト イヨト イヨト

Unified model of radio halos and relics

Cluster radio emission varies with dynamical stage of a cluster:

- Cluster relaxes and develops cool core: radio mini-halo develops due to hadronically produced CR electrons, magnetic fields are adiabatically compressed (cooling gas triggers radio mode feedback of AGN that outshines mini-halo → selection effect).
- Cluster experiences major merger: two leading shock waves are produced that become stronger as they break at the shallow peripheral cluster potential → shock-acceleration of primary electrons and development of radio relics.
- Generation of morphologically complex network of virializing shock waves. Lower sound speed in the cluster outskirts lead to strong shocks → irregular distribution of primary electrons, MHD turbulence amplifies magnetic fields.
- Giant radio halo develops due to (1) boost of the hadronically generated radio emission in the center (2) irregular radio 'gischt' emission in the cluster outskirts.

イロト イポト イヨト イヨト

Low-frequency radio emission from clusters Window into current and past structure formation

Our unified model accounts for ...

- correlation between merging clusters and giant halos, occurrence of mini-halos in cool core clusters
- observed luminosities of halos/relics for magnetic fields derived from Faraday rotation measurements
- observed morphologies, variations, spectral and polarization properties in radio halos/relics

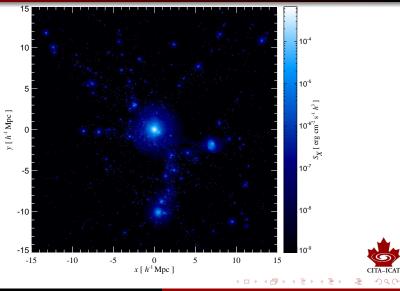

How we can make use of this information:

- Radio relics: produced by primary accelerated CR electrons at formation shocks → probes current dynamical, non-equilibrium activity of forming structures (shocks and magnetic fields)
- Central radio halos: produced by secondary CR electrons in hadronic CR proton interactions → tracing time-integrated non-equilibrium activity, modulated by recent dynamical activities

Summary

- Characteristics of the CR pressure in clusters:
 - CR proton pressure traces the time integrated non-equilibrium activities of clusters and is modulated by recent dynamical activities.
 - The pressure of primary, shock-accelerated CR electrons resembles current accretion and merging shocks in the virial regions.
- Onified model for the generation of giant radio halos, radio mini-halos, and relics:
 - Giant radio halos are dominated in the center by secondary synchrotron emission.
 - Transition to the radio emission from primary electrons in the cluster periphery.
- We predict GLAST to detect ~ ten γ-ray clusters: test of the presented scenario
